# Nernst equation

$$E = \frac{RT}{ZF} \ln \frac{[C]_{out}}{[C]_{in}}$$

R (Gas Constant) = 8.314472 (J/K·mol)

T (Absolute Temperature) = t °C +  
273.15 (°K)

Z (Valence)

F (Faraday's Constant) = 9.6485309×10<sup>4</sup>  
(C/mol)

[C]<sub>out</sub> (Outside Concentration, mM)

[C]<sub>in</sub> (Inside Concentration, mM)

$$E_{K^+}$$

$$E_{eq,K^+} = 61.54mV \log \frac{[K^+]_o}{[K^+]_i}$$

$$E \text{ (mV)} = - 61.\log (C_i/C_o)$$

$E$  = Equilibrium potential for a univalent ion

$C_i$  = conc. inside the cell.

$C_o$  = conc. outside the cell.

# Goldman Hodgkin Katz equation

$$E_m = \frac{RT}{F} \ln \left( \frac{P_{Na^+} [Na^+]_o + P_{K^+} [K^+]_o + P_{Cl^-} [Cl^-]_i}{P_{Na^+} [Na^+]_i + P_{K^+} [K^+]_i + P_{Cl^-} [Cl^-]_o} \right)$$

**I** = Conc. inside

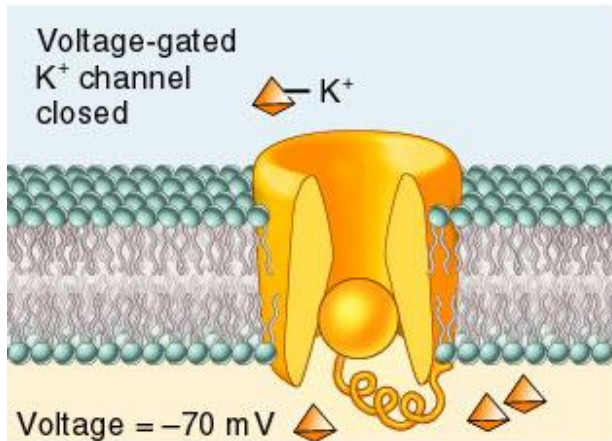

**O** = Conc. outside

**P** = permeability of the membrane to that ion.

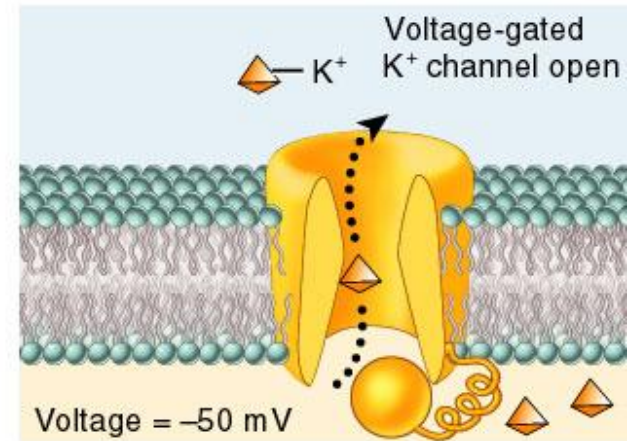

Extracellular fluid

Plasma membrane

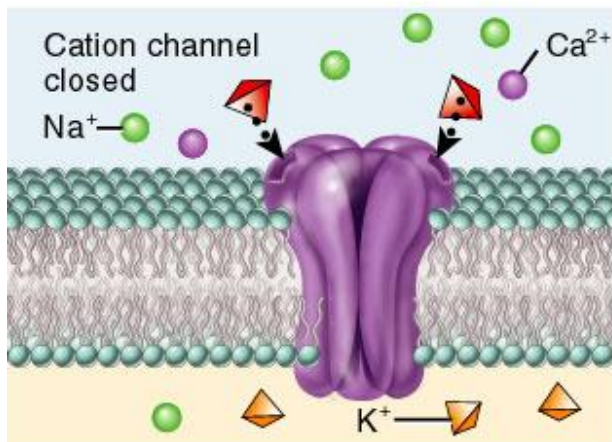

Cytosol

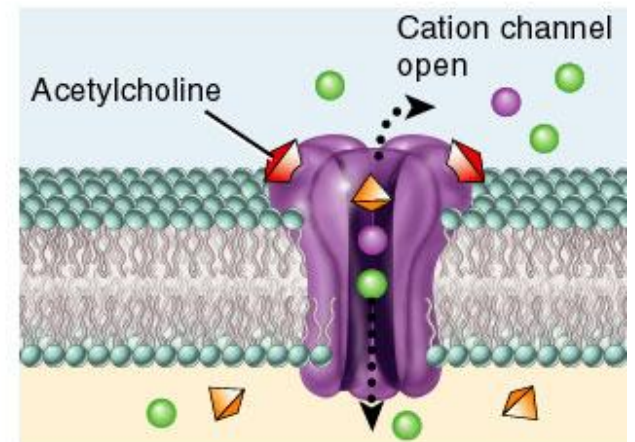

Change in  
membrane potential  
opens the channel

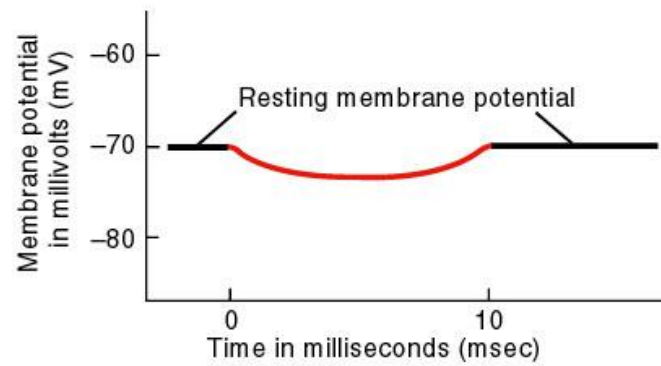

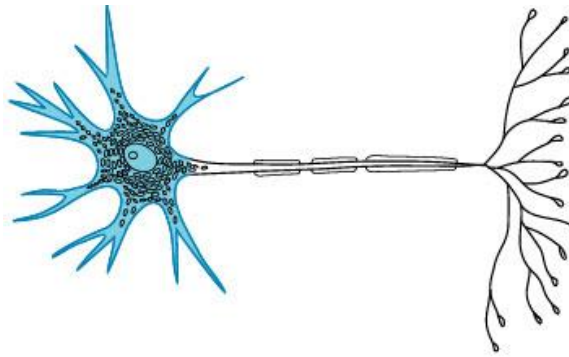

(a) Voltage-gated channel

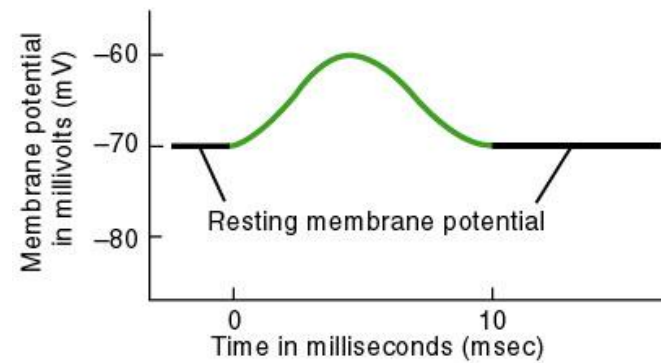

Chemical stimulus  
opens the channel

(b) Ligand-gated channel

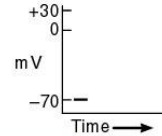

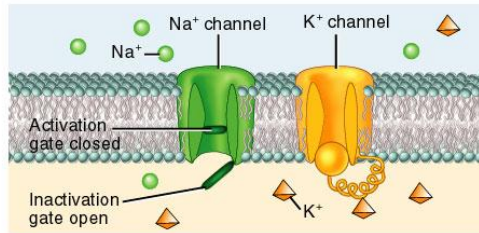

(a) Hyperpolarizing graded potential

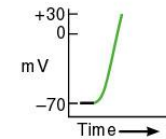

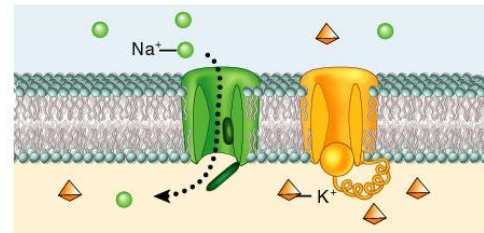

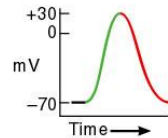

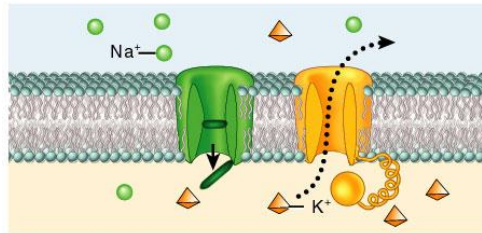

(b) Depolarizing graded potential

□ Extracellular fluid    ■ Plasma membrane    □ Cytosol

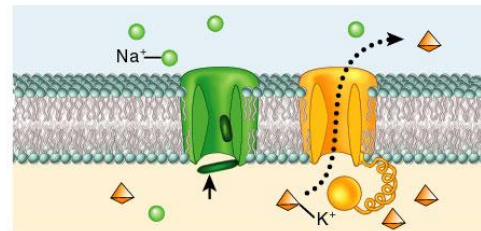

- 1. Resting state:**  
All voltage-gated  $\text{Na}^+$  and  $\text{K}^+$  channels are closed.

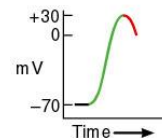

- 2. Depolarizing phase:**  
Depolarization to threshold opens  $\text{Na}^+$  channel activation gates.  $\text{Na}^+$  inflow further depolarizes the membrane, opening more  $\text{Na}^+$  channel activation gates.

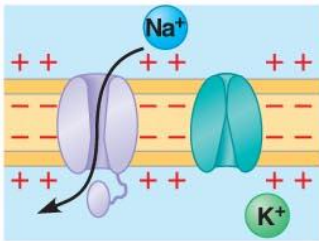

- 4. Repolarization continues:**  
 $\text{K}^+$  outflow restores resting membrane potential.  $\text{Na}^+$  channel inactivation gates open. Return to resting state when  $\text{K}^+$  gates close.

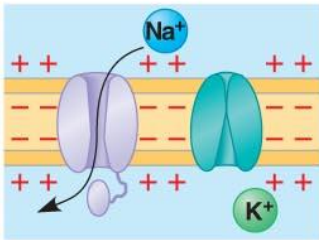

- 3. Repolarizing phase:**  
 $\text{Na}^+$  channel inactivation gates close and  $\text{K}^+$  channels open. Outflow of  $\text{K}^+$  causes repolarization.

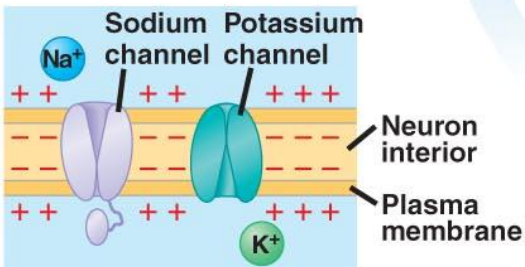

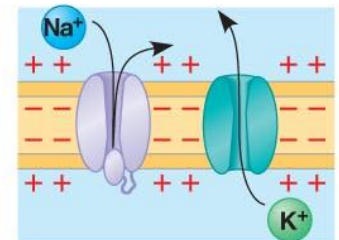

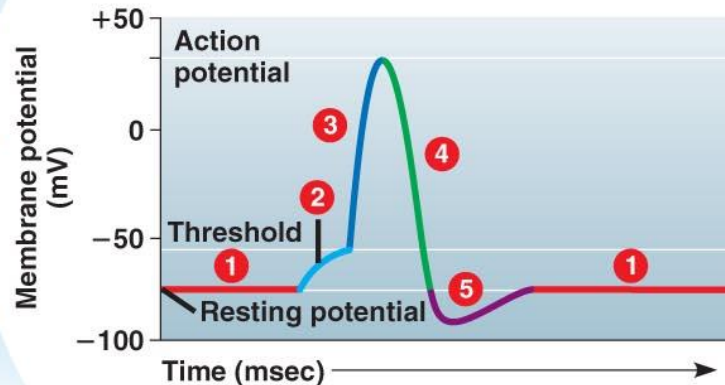

- 3** Additional Na<sup>+</sup> channels open, K<sup>+</sup> channels are closed; interior of cell becomes more positive.

- 2** A stimulus opens some Na<sup>+</sup> channels; if threshold is reached, action potential is triggered.

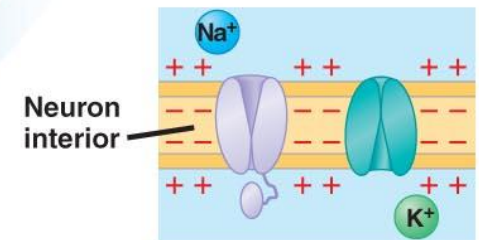

- 1** Resting state: voltage-gated Na<sup>+</sup> and K<sup>+</sup> channels closed; resting potential is maintained.

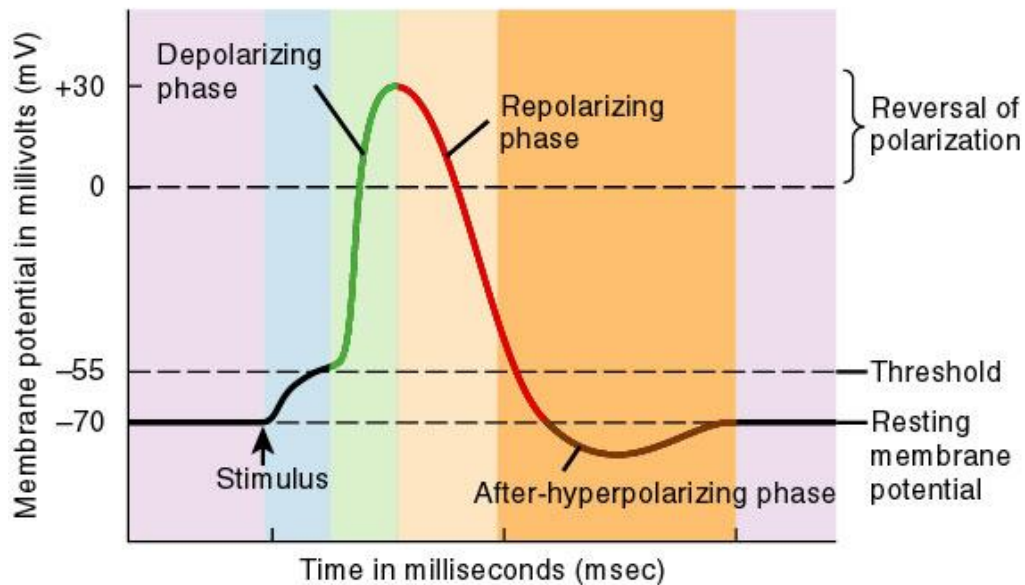

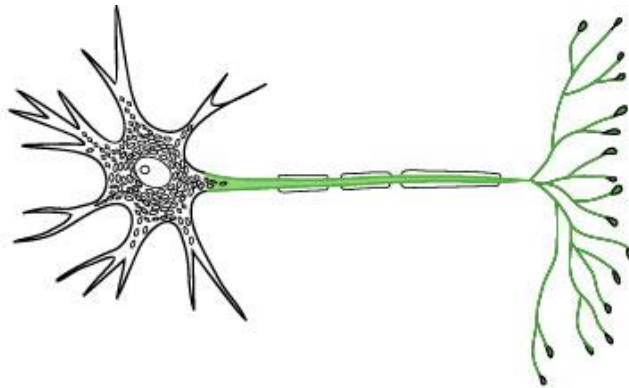

- 4** Na<sup>+</sup> channels close and inactivate. K<sup>+</sup> channels open, and K<sup>+</sup> rushes out; interior of cell more negative than outside.

- 5** The K<sup>+</sup> channels close relatively slowly, causing a brief undershoot.

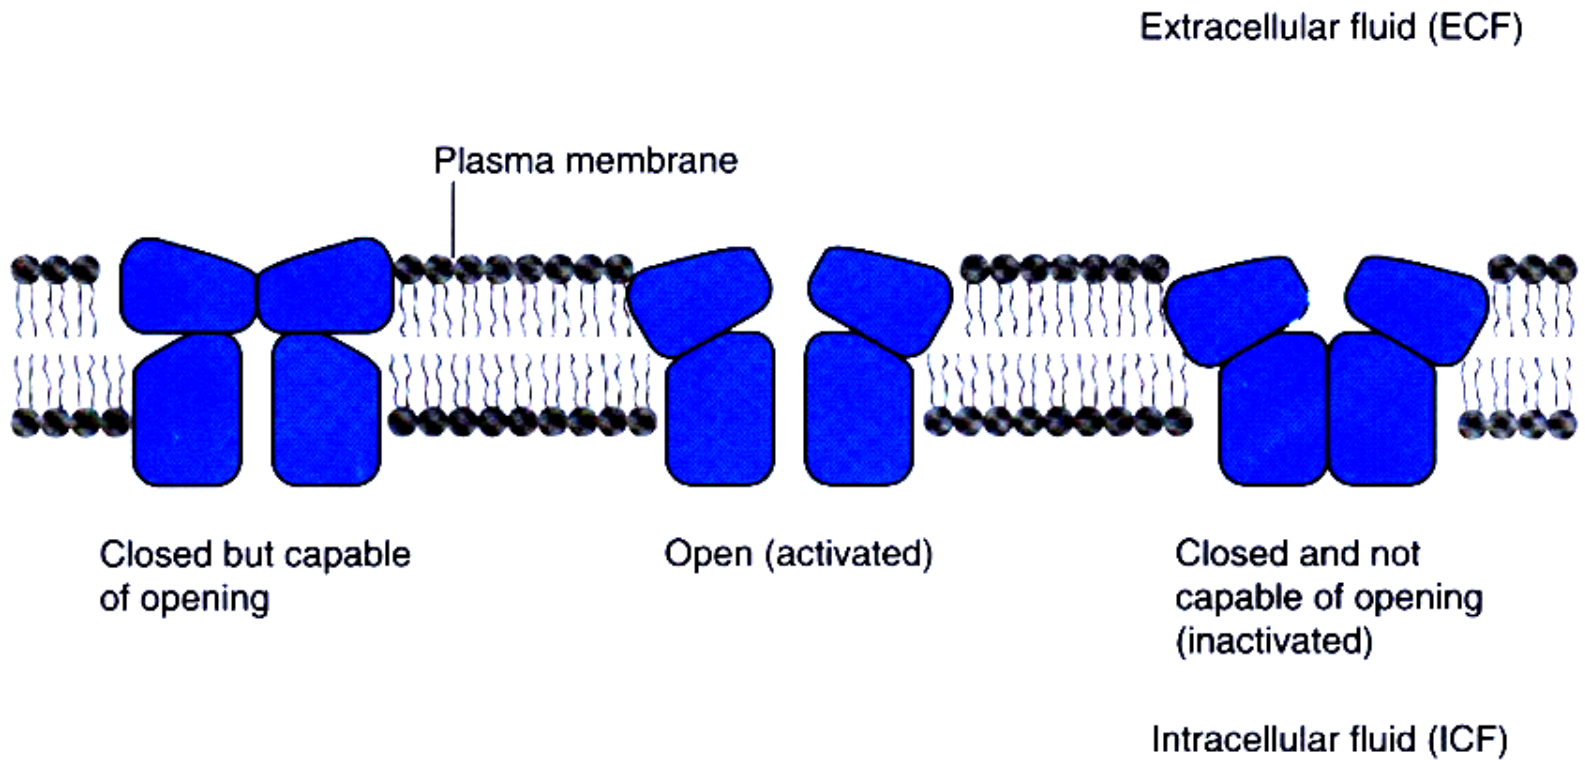

- 1** Return to resting state.

### Key:

- Resting membrane potential: Voltage-gated  $\text{Na}^+$  channels are in the resting state and voltage-gated  $\text{K}^+$  channels are closed
  - Stimulus causes depolarization to threshold
  - Voltage-gated  $\text{Na}^+$  channel activation gates are open
  - Voltage-gated  $\text{K}^+$  channels are open;  $\text{Na}^+$  channels are inactivating
  - Voltage-gated  $\text{K}^+$  channels are still open;  $\text{Na}^+$  channels are in the resting state
- Absolute refractory period
- Relative refractory period
